

Nest AI Inspection Report

Executive Summary & Identification:

The image analysis confirmed the presence of a nest, but it was not a yellowjacket wall void nest as initially suspected. The nest appears to be made of paper-like material, located inside a wall void, and there are no signs of yellowjackets. This suggests that the nest is not active. Safe dust treatment procedures and criteria for professional extermination have been reviewed.

Treatment Guidelines & Professional Thresholds:

Based on the findings, the nest is not a yellowjacket wall void nest. The nest material is fluffy and irregular, which is typical of a non-hymenopteran nest. The nest is located inside a wall void, which is a common location for nests, but no yellowjackets are currently present. Safe insect dust treatment procedures should be followed, such as treating the nest after dark and not sealing the entrance until all insects are dead. For wall voids, it is recommended to call a professional exterminator due to the potential risk of stinging hazards from trapped yellowjackets. Preventive measures include keeping trash cans closed and clean, and using specialized traps to capture yellowjackets.
